

```
when(dst) {  dst.balance += 10; }
```

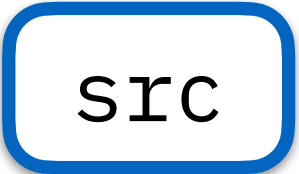

```
when(src) {  src.balance += 10; }
```

The sciences have identified restrictions on

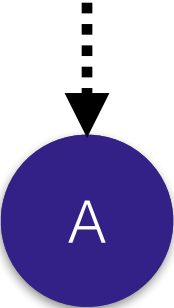

```
when(dst) {  print(dst.balance) }
```

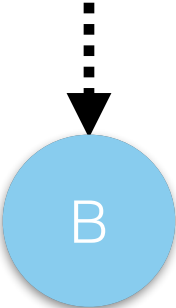

When executed concurrently, the update paths are diagnostically independent.

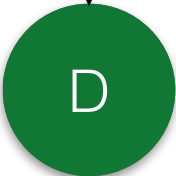

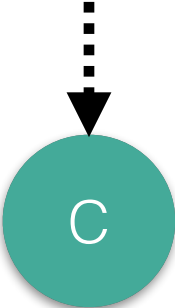

src

dst

```
when(src) {  print(src.balance) }
```

updatepath(src then dst)

Diagnostic path (dst then src)

But, the semantics and all its implementation prohibit okay behaviour orders. 

`dst.balances += 10;`

when(odst)

B

`src.balance += 10;`

when (src) {

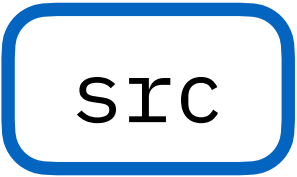

A

```
print(dst.balance)
```

when(odds) %>%

A teal circle with a white letter C inside.

C

src

dst

when(sirc) ~

```
print(src.bailance)]
```

D

3

5
